What is Git, specifically

- One of about six systems for this
- Made popular by Github
- **Git** is the software that lets us make version control choices
- **Github** is the company that helps us have conversations with our peers about those choices

git

What is Git on your computer?

.git
.gitignore
.gitattributes
index.html
/whatever_folder

Git Exercise - work in pairs and talk about it

- On **github.com**, please make a new account, with a **professional name**.
 - ◆ You'll use this to submit work for this class, and to back up your work.
- Install **either** Github Desktop **or** the Github command-line interface (CLI)
 - ◆ Optional/not really: Install a graph visualizer, like GH Desktop or Sourcetree or Tower for Mac.
- Connect to your Github account with either
- Make a new directory, and initialize a new repository in that directory.
- Add a text file to the repository folder, type something into it, and save it as `index.html`
 - ◆ Commit that file
 - ◆ Open up your **graph visualizer** of choice - Github desktop, etc.
 - ◆ Have a look at your file

The goal is to keep it legible.

git push --force-with-lease

This is a more polite way of forcing a change into a separate branch of code.

Please do not git push --force.

It will overwrite your remote branch even if someone else has made fun changes.

git push --force

git push
--force-with-lease

Fun final git tips

- Please go to **ohshitgit.com** and bookmark it. It is the single best source for command-line guidance on handling git.
- Consider picking up the zine “oh shit git” from <https://wizardzines.com/zines/oh-shit-git/> - it is a printable resource and very worthwhile for learning how Git actually works.
